Abstract: Simple queueing systems are presented as candidates for solution by both analytical and simulation methods. The limitations of the analytical approach are contrasted with the stochastic nature of a simulation solution. A sequence of problems leads from a model which is easily solved analytically to a model which is not amenable

Solution: This problem indicates the usefulness of the z-transform in the calculation of the distribution of the sum of variables. We have proven that the ZT of the sum of independent random variables is the product of their individual z-transforms. Thus, $P(z) = \prod_{i=1}^n P_i(z) = \prod_{i=1}^n e^{-a_i(1-z)} = e^{-\sum_{i=1}^n a_i(1-z)}$; where $\sum_{i=1}^n a_i = \dots$

QUEUING THEORY

Queuing theory is the mathematical study of queuing, or waiting in lines. Queues contain customers (or “items”) such as people, objects, or information. Queues form when there are limited resources for providing a service. For example, if there are 5 cash registers in a grocery store, queues will form if more than 5 customers wish to pay for their items at the same time.
